1 REAL TIME DEBUGGER INTERFACE FOR EMBEDDED SYSTEMS

2

3

# BACKGROUND OF THE INVENTION

4

6

7

8

9

# 5 1. Field of the Invention

The invention relates to systems and methods for debugging software in real time. More particularly, the invention relates to systems and methods for the real time debugging of firmware in embedded systems, e.g. ASIC chips having one or more processors on a single chip.

<del>1</del>7

18

19

20

21

22

23

### 2. State of the Art

Software debugging may be accomplished in a number of ways, some of which are not performed in real time. A traditional debugging technique is to step through program instructions at a rate much slower than the rate at which the program is designed to run in real time. By stepping through the program instructions one-by-one, errors can be observed as they happen and the program code lines executed immediately prior to the error can be analyzed to find the cause of the error. This technique is not helpful, however, if the error in program execution is the result of timing errors or other types of errors which only occur when the program is running at real time speed. As used herein, the term "real"

. 1 time" means the rate at which a program must execute in order to 2 process the incoming data rate which may be quite high.

3

4

5

6

7

8

9

A widely used technique for debugging a program which is running in real time is called "tracing". Tracing involves recording the transactions performed by the computer as it executes the program code. The trace of activities performed by the computer during the time of a failure can be a useful guide in isolating possible causes of the failure.

Another useful debugging tool is to set breakpoints at selected places in the program. The breakpoints trap the flow of the software and provide insight into whether, when, and how certain portions of the software are entered and exited. An analysis of the flow of the software can provide information which is useful in isolating bugs.

18

19

20

21

22

23

24

Many state-of-the-art tracing and trapping methods are accomplished by a debug support circuit which is connected to the system bus, i.e. the bus which couples the CPU to memory. See, for example, U.S. Patent Number 5,491,793 to Somasundaram et al. entitled "Debug Support in a Processor Chip." Connecting a debug circuit to the system bus is convenient because addresses, instructions, and data can be accessed via the system bus.

1 However, coupling the debug support circuit to the system bus

2 increases the electrical load on the bus and interferes with the

3 operation of the bus. Moreover, operation of the system bus may

4 interfere with operation of the debug support circuit. In

5 addition, the system bus may not provide all the information

6 necessary for debugging a program running on a CPU which uses

7 internal cache. These CPUs will not access the system bus if the

8 information they need is available in cache. If an error occurs

while the CPU is accessing internal cache, the debug support

9

10

12

18

19

20

21

22

23

circuit will not be able to access the information it needs.

Another tracing and trapping method is disclosed in U.S.

Patent Number 5,833,310 to Whistel et al. entitled "On-Chip In-Circuit-Emulator Memory Mapping and Breakpoint Register Modules."

According to this method, an internal bus controller is coupled to the memory address bus and a match register. When a memory address written to the address bus matches an address in the match register, a memory mapping module maps a memory cycle to an external debug memory. The user can set specific bus event conditions for which memory is mapped by writing to a set of breakpoint registers. A disadvantage of this method is that it requires an additional set of I/O pins for the chip so that the external debug memory can be coupled to the chip. This may

1 require a significant number of pins since the addresses to be 2 mapped may be 32 or 64 bits wide.

3

4 Still another tracing and trapping method is disclosed in U.S. Patent Number 5,513,346 to Satagopan et al. entitled "Error 5 6 Condition Detector for Handling Interrupt in Integrated Circuits Having Multiple Processors." According to this method, an 7 8 interrupt processor controller intercepts all interrupts and 9 routes them to the appropriate processor in a multiprocessor chip. **伊州山西地上沙山山西山西** The interrupt processor controller includes logic which determines when an interrupt will cause an error because a previously instigated interrupt has not been cleared. When such an error is detected, a bit is set in an error detect register, the bit corresponding to an interprocessor interrupt channel. The bits in the register are ORed and a single bit output indicates the occurrence of an error. The register may then be examined to 17 determine the location of the interrupt error in the executing 18 code. This method does not interfere with the system bus and does 19 not require very many additional pins on the chip. However, the 20 debugging information that it provides is limited.

21

The Motorola MPC-860 PowerQuicc™ includes a program
development system interface port which provides a three bit
output indicative of the state of the program execution as the

1 program is being executed. The MPC-860 is a 40 mHz communications

2 controller but the development system interface port is only

3 operable at a rate of 4 mHz. Thus, the port can not be used for

4 real time debugging. The specifications for the MPC-860 are found

5 in the "MPC-860 POWERQUICC USER'S MANUAL", Copyright 1996

6 Motorola, Inc., Schaumberg, IL, the complete disclosure of which

7 is incorporated herein by reference.

8

9

ASIC design using one or more embedded processors poses additional debugging challenges. The prior art methods of trapping instructions at a given point in time implies that the system must be stopped to allow debugging of firmware. Once the system is stopped, however, real time events and their timing relationships are lost. If there is a firmware bug which is only identifiable in the presence of live traffic (during real time operations) it is necessary to obtain contextual information about the error before the firmware is changed.

18

19

17

# SUMMARY OF THE INVENTION

20

21

22

23

It is therefore an object of the invention to provide a debugging interface for tracing instructions without loss of real time context and event interaction.

24

1 It is also an object of the invention to provide a debugging 2 interface which does not interfere with the operation of a 3 processor or system bus.

It is another object of the invention to provide a debugging interface which does not require many additional pins on a processor chip.

It is a further object of the invention to provide a debugging interface which provides access to a substantial amount of information about the executed instructions.

In accord with these objects which will be discussed in detail below, the debugging interface of the present invention includes a first decoder coupled to the sequencer of a processor and to the Instruction RAM (IRAM) of the processor. The first decoder, according to the invention, provides a real time three bit output on a cycle by cycle basis which is indicative of the processor activity during the last clock cycle. According to a presently preferred embodiment, the three bit output indicates seven different conditions regarding processor activity. In particular, the three bit output indicates whether or not a new instruction has been executed since the last clock cycle, and if a new instruction has been executed, whether the last instruction

executed by the processor was an immediate jump, a jump to
register, or a branch taken. In addition, the three bit output
will indicate whether execution of the instruction resulted in an
exception. By recording this three bit output over time, and
comparing it to the actual instructions listed in the program
code, important debugging information is obtained about a program
which was running in real time.

8

9

17

18

19

20

21

22

23

24

According to a preferred embodiment of the invention, a second decoder and an event history buffer are coupled to the cause register of the sequencer of the processor. In particular, the second decoder is coupled to the enable input of the history buffer and the cause register is coupled to the data input of the history buffer. The second decoder decodes the contents of the cause register and enables the history buffer whenever the contents of the cause register indicates an exception, a jump register instruction, or a change in the status of an interrupt line. Whenever the history buffer is enabled, information from the cause register and the program counter is loaded into the buffer. By recording the contents of the history buffer over time, and comparing the information to the actual program code, additional important debugging information is obtained about a program which was running in real time. According to this preferred embodiment of the invention, the seventh condition

1 indicated by the three bit output of the first decoder is whether

an exception was encountered without writing to the history

3 buffer.

每日日日後年8年4日5月6日

According to the presently preferred embodiment, each entry in the event history buffer is forty-four bits. Each forty-four bit entry in the history buffer includes the current sixteen bit time stamp, twenty three bits from certain fields of the cause register or program counter, one bit indicating whether the entry is related to a jump or an exception, two bits identifying the processor number (in a multiprocessor system), one bit identifying whether the history buffer has overflowed, and a time stamp rollover bit. The history buffer preferably has a depth of at least sixteen entries.

An exemplary implementation of the debugging interface is embodied on an ASIC chip having three processors. Each processor is provided with two decoders as described above and a single event history buffer is provided on the chip. Nine pins on the chip are used to provide access to the three bit outputs of each first decoder. Three pins on the chip provide serial access (data, clock, and enable) to the contents of the event history buffer. These twelve pins on the chip allow a diagnostic device to be coupled to the chip during real time operations without

1 interfering with the operation of the chip. The outputs of the

2 first decoders and the contents of the event history buffer can be

recorded over time by the diagnostic device to provide a real time 3

4 record of the processing events occurring in the chip during real

5 This real time record taken together with knowledge of the

program code being executed provides a true picture of the 6

processors' execution sequence in real time and thereby expedite

8 debugging of code.

9

7

Additional objects and advantages of the invention will become apparent to those skilled in the art upon reference to the detailed description taken in conjunction with the provided figures.

# BRIEF DESCRIPTION OF THE DRAWINGS

18

19

Figure 1 is a schematic block diagram of an exemplary implementation of a real time debugger interface according to the invention; and

20

21

22

23

Figure 2 is a schematic block diagram of a debugging system coupled to a chip embodying a real time debugger interface according to the invention.

24

#### DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

2

3

4

6

8

9

1

Referring now to Figures 1, an exemplary ASIC chip 10 incorporating a debugger interface according to the invention 5 includes three processors 12a, 12b, 12c, sharing a common clock 16 via a clock bus 17. Each processor includes an instruction RAM 7 (IRAM) 18a, 18b, 18c, an arithmetic logic unit (ALU) 20a, 20b, 20c, and a "sequencer" 22a, 22b, 22c. Each sequencer includes a program counter 24a, 24b, 24c and a cause register 26a, 26b, 26c. Each program counter contains an index of the instructions in an associated IRAM and a pointer to the index as the instructions are executed by the processor. The cause registers store current information about interrupts, exceptions, and other processor functions.

17

18

19

20

According to one aspect of the invention, a first decoder 28a, 28b, 28c is coupled to each IRAM 18a, 18b, 18c, and to each sequencer 22a, 22b, 22c, i.e., to each program counter and each cause register. Each first decoder has a three bit output 30a, 30b, 30c which is available off the chip 10 via three pins (0, 1, 2) in real time.

22

23

24

21

As mentioned above, the three bit output of each first decoder 28 provides an indication of the processor activity during

- 1 the last clock cycle. Thus, the decoder 28 is arranged to
- 2 indicate whether the program counter has moved its pointer to a
- 3 new instruction. The decoder also decodes the instruction in the
- 4 IRAM to provide information about the instruction, and decodes the
- 5 contents of the cause register to provide an indication of an
- 6 exception encountered during the execution of an instruction.
- 7 According to a presently preferred embodiment, the first decoder
- 8 28 generates a three bit output which is interpreted as shown in
- 9 Table 1, below.

6

7

8

9

10

11

Output	Mnemonic	Description
000	NC	No Change
001	INC	Program Counter Increment
010	JI	Program Counter Jump Immediate
011	JR	Program Counter Jump Register
100	ECP	Exception Encountered
101	PBT	Program Counter Branch Taken
110	RSD	Reserved
111	ENH	Exception Encountered, No History Buffer
		Entry Written

Table 1

The output 000 indicates that there has been no change in the processor since the last clock cycle; i.e., the processor has not processed a new instruction and the program counter pointer has not changed. The output 001 indicates that the processor has processed the next instruction in the program; i.e., the program counter pointer has incremented to the next instruction in the index. The output 010 indicates that the last instruction processed by the processor was a "hard coded" jump to an instruction; i.e., the instruction in IRAM pointed to by the

1 program counter includes code indicating that it is a jump instruction to an absolute address in the program. The output 011 2 3 indicates that the last instruction processed by the processor was 4 a jump to an instruction based on the contents of a register; 5 i.e., the instruction in IRAM pointed to by the program counter 6 includes code indicating that it is a jump instruction to a 7 location in the program determined by the value of a variable. The output 100 indicates that since the last clock cycle the 8 9 processor has encountered an interrupt or an exception; i.e., the 10年前至19年4日5月10日 contents of the cause register contain code which indicates an interrupt or exception. The output 101 indicates that the last instruction processed by the processor was a pc branch taken; i.e., the instruction in IRAM pointed to by the program counter includes code indicating that it is a branch back to another instruction. The output 110 is not presently used, but is reserved for future use. The output 111 indicates that since the 17 last clock cycle the processor has encountered an interrupt or an 18 exception; and that no entry was made in the history buffer 19 20 The operation of the first decoder 28 and its output is

2223

below in Table 2.

21

illustrated with reference to a simple code listing which is shown

5

6

7

8

9

LINE NUMBER	INSTRUCTION
10	Input A
20	B=5
30	C=2
40	D=B+C
50	If D=7 then Goto 70
60	Goto A*10
70	B=4
80	Goto 30
90	End

Table 2

The listing in Table 2 has one "immediate" or "hard coded" jump instruction at line 80 and a conditional branch at line 50. It also has one jump instruction, line 60, based on the contents of a register, i.e. the value of A which is input at line 10. The three bit output of the first decoder during execution of the instructions shown in Table 2 is illustrated in Table 3 below where the values of variables A, B, C, and D are also shown.

10

Current Line	Next Line	A	В	С	D	Mnemonic	Three Bit Output
10	20	?	?	3	?	INC	001
20	30	?	5	?	?	INC	001
30	40	?	5	2	?	INC	001
40	50	?	5	2	7	INC	001

50	60	?	4	2	6	INC	001
60	?	?	4	2	6	JR	011

Table 3

When the first instruction (listed in line 10) is executed, the first decoder indicates that a program counter increment (INC) in the execution of the program has occurred and shows an output of "001". As the program progresses from the instruction on line 10 through the instruction on line 40, the first decoder continues to indicate that a program counter increment (INC) in the execution of the program has occurred and continues to show an output of "001". When the instruction on line 50 is executed, the first decoder indicates that a program counter branch taken (PBT)

1 has occurred and shows an output of "101". As seen in Tables 2 2 and 3, the program branches to line 70 because the conditional 3 expression of line 50 is true based on the variable D=7. Upon 4 execution of line 70, the first decoder indicates that a program 5 counter increment (INC) in the execution of the program has 6 occurred and shows an output of "001". When the instruction on 7 line 80 is executed, the first decoder indicates that an immediate 8 jump (JI) has occurred and shows an output of "010". As seen in 9 Tables 2 and 3, the program jumps to line 30. When the 海里特可提早份子4日本直接。1 instructions on lines 30 and 40 are executed, the first decoder indicates that a program counter increment (INC) in the execution of the program has occurred and shows an output of "001". When line 50 is executed (now for the second time) the first decoder indicates that a program counter increment (INC) in the execution of the program has occurred and shows an output of "001" because the condition (D=7) for the jump in line 50 is no longer valid. Line 60 is now executed and a jump to a location stored in a 18 register occurs. The first decoder therefore indicates a jump to 19 register (JR) by showing an output of "011".

20

Referring once again to Figure 1, according to another aspect of the invention, each cause register 26a, 26b, 26c is coupled to the data input D of an event history buffer 14 and a second decoder 32a, 32b, 32c is coupled to each cause register and to the

1 enable input E of the history buffer 14. The clock 16 provides 2 the common clock signal to the clock input C of the history buffer 14 via the clock bus 17, and a timestamp register 19 is also 3 coupled to the clock bus 17. The contents of the history buffer 4 5 14 are made available off chip by three pins for the data, clock, 6 and enable (D, C, E) of the history buffer 14. According to this 7 aspect of the invention, when certain conditions are detected by . 8 one of the second decoders 32, the history buffer is enabled via 9 the appropriate decoder, and information from the cause register, 10 the timestamp register, and the program counter is stored in the history buffer. More particularly, the second decoder 32 enables the history buffer whenever the first decoder contains code which indicates that the processor is processing an instruction to jump to a location stored in a register, whenever the first decoder contains code indicating an exception was encountered, and whenever the first decoder contains code indicating a change in state of an interrupt line.

18

19

20

21

22

According to a presently preferred embodiment, when the history buffer is enabled, it captures forty-four bits of information from the cause register or program counter, and the timestamp register. The forty-four bits of information are preferably organized as illustrated in Table 4 below.

24

23

43	42	41	40	_	18	17	16	15	- 0
Mode	Pr	coc	Caı	ıse	/PC	HOVRF	TR	Time	Stamp

Table 4

2

3

4

5

6

15

16

17

18

19

20

21

1

The first bit, bit location 43, is a mode identifier indicating whether the entry being stored has program counter information or cause register information. A two bit processor identification number is stored in binary form at bit locations 42, 41. This number is used to indicate which processor's information is being stored (in the case of a multiprocessor system). The next twenty-three bits at bit locations 40 through 18 are used to store cause register information or program counter information depending on the mode as explained above. If program counter information is being stored, the contents of the program counter are stored at bit locations 40 through 18. register information is being stored, bit location 40 is used to indicate whether the exception occurred while the processor was executing an instruction in the branch delay slot. (This applies to pipelined processors such as RISC processors.) Bit locations 39 through 35 are used to store processor related exception conditions. Bit locations 34 through 18 are used to store an indication of all pending interrupts (external, software, co-The HOVRF field at bit location 17 is used to indicate processor.

1 whether the internal event history buffer has overflowed. The TR

2 bit 16 is used to indicate a timestamp rollover and bits 15

3 through 0 are used to store a sixteen bit timestamp. According to

4 the presently preferred embodiment, the forty-four bits captured

in the history buffer 14 are serially output on data pin D over

6 forty-four clock cycles (bit serial output).

7

8

9

5

As mentioned above, the event history buffer records information when an event (either an unmasked exception or a PC jump register instruction) has occurred. According to a presently preferred embodiment, this requires an additional mask register per cause register and a free running timestamp counter. The event masks are provided by a JTAG test register load instruction in the static debug interface. When the cause register bits corresponding to an exception are unmasked or a PC jump register instruction is encountered, an entry is made in the history buffer.

19

20

21

22

23

Those skilled in the art will appreciate that the outputs of the first decoder 28 and the contents of the history buffer 14 provide a relatively complete indication of each processor's execution sequence in real time, particularly when viewed in light of the actual program code which is being executed. Therefore,

1 according to the invention, a debugging system may be coupled to
2 the first decoders and history buffer as illustrated in Figure 2.

Turning now to Figure 2, the outputs 30a, 30b, 30c of the first decoders and the D,C,E terminals of the history buffer are coupled to a debugging computer 44 which preferably has a copy of the program code stored therein. The three-bit outputs 30a,30b, 30c of the first decoders and the D,C,E terminals of the history buffer are preferably coupled to an interface buffer 40 which is coupled by a serial, parallel, or network connection 42 to the debugging computer 44. The interface buffer 40 is a rate decoupling buffer. In a present embodiment of the invention, the debugger interface is provided on a 100 MHz three processor system. In that system, the data rate for reading the event history buffer is approximately 1 gigabit/sec. Current PCs cannot keep up with that data rate. Therefore, the buffer 40 is provided to prevent the loss of event history data.

As the program is running on the ASIC 10, the debugging computer 44 collects information from the first decoders and the history buffer. The information collected by the computer 44 is associated with each line of code being executed by the ASIC by stepping through the copy of the code which is stored in the computer 44. When a bug is encountered, the complete history of

instruction execution leading up to the failure can be reviewed with the computer 44. The debugging system is non-invasive and permits debugging of programs operating in real time.

There have been described and illustrated herein embodiments of a real time debugger interface for embedded systems. While particular embodiments of the invention have been described, it is not intended that the invention be limited thereto, as it is intended that the invention be as broad in scope as the art will allow and that the specification be read likewise. Thus, while particular encoding schemes have been disclosed with reference to the first decoder output and the history buffer contents, it will be appreciated that other encoding schemes could be utilized provided that they achieve substantially the same results as described herein. Also, while the invention has been illustrated with reference to a three-processor ASIC chip, it will be recognized that the invention may be applied in other types of chips having greater or fewer processors. Moreover, while particular configurations have been disclosed in reference to the indications provided by the first decoders, it will be appreciated that other configurations could be used as well, provided that they achieve substantially the same results as described herein. It will therefore be appreciated by those skilled in the art that

- 1 yet other modifications could be made to the provided invention
- 2 without deviating from its spirit and scope as so claimed.

#### Claims:

- 1. A processor having a real time debugging interface, said processor comprising:
- a) instruction memory means for storing instructions to be executed by said processor;
- b) program counter means coupled to said instruction memory means for indexing said instructions;
- c) cause register means for indicating information regarding interrupts and exceptions; and
- d) first decoder means for indicating information about an instruction executed by said processor during a clock cycle, said first decoder means being coupled to said instruction memory means, said program counter means, and said cause register means, said first decoder means having a first output, wherein

said first output provides information regarding activity of said processor in real time.

2. A processor according to claim 1,

said information regarding processor activity includes information as to at least one of a jump instruction has been executed, a jump instruction based on the contents of a register has been executed, a branch has been taken, and an exception has been encountered.

- 3. A processor according to claim 1, wherein: said clock cycle is a processor clock cycle, and said first decoder means updates said information about each instruction executed by said processor for each said processor clock cycle.
- 4. A processor according to claim 3, wherein: said information about each instruction executed by said processor includes an indication whether or not an instruction has been executed since a previous processor cycle.
- 5. A processor according to claim 1, wherein: said first output is a three bit parallel output.

- 6. A processor according to claim 1, further comprising:
- e) second decoder means coupled to said cause register means for indicating information about contents of said cause register means, said second decoder means having a second output; and
- f) event history buffer means for storing information regarding processor events, said event history buffer means having a data input, a data output, and an enable input, said data input being coupled to said cause register means and said enable input being coupled to said second output, wherein

said second decoder means decodes contents of said cause register means and enables said event history buffer means to capture contents of said cause register means when contents of said cause register means indicate a particular event.

7. A processor according to claim 6, wherein:

said second decoder means enables said event history buffer means when contents of said cause register means indicate an event including at least one of a change in status of an interrupt line, an internal processor exception, and a jump instruction based on the contents of a register.

8. A processor according to claim 6, wherein:

said data output of said event history buffer means is a bit serial output.

9. A processor according to claim 6, wherein:

said processor is embodied on a chip having a plurality of pins,

said first output and said data output are provided via some of said plurality of pins.

10. A processor according to claim 9, wherein: said first output is an n-bit parallel output, and said data output is a serial output.

- 11. An embedded system having a plurality of processors and a real time debugging interface, said system comprising:
- a) a plurality of instruction memory means for storing instructions to be executed by a respective one of said plurality of processors;
- b) a plurality of program counter means, each coupled to a respective one of said plurality of instruction memory means for indexing contents of said instruction memory means;
- c) a plurality of cause register means for indicating information regarding interrupts and exceptions for a corresponding one of said plurality of processors, each of said cause register means being coupled to a respective one of said processors; and
- d) a plurality of first decoder means, each said first decoder means coupled to a respective one of said instruction memory means, to a respective one of said program counter means, and a respective one of said cause register means, each said first decoder means for indicating information about an instruction executed during a clock cycle by a respective one of said processors, each said first decoder means having a first output, wherein

each said first output provides information regarding activity of said processor in real time.

- 12. An embedded system according to claim 11, wherein:
  said information regarding processor activity includes
  information as to at least one of a jump instruction has been
  executed, a jump instruction based on the contents of a register
  has been executed, a branch has been taken, and an exception has
  been encountered.
- 13. An embedded system according to claim 11, wherein:
  said clock cycle is a processor clock cycle, and
  each said first decoder means updates said information about
  each instruction executed by a respective processor for each said
  processor clock cycle of said respective processor.
- 14. An embedded system according to claim 13, wherein:

  each said information about each instruction executed by a
  respective processor includes an indication whether or not an
  instruction has been executed since a previous processor cycle of
  said respective processor.
- 15. An embedded system according to claim 11, wherein:
  each of said first outputs is a three bit parallel output.

- 16. An embedded system according to claim 11, further comprising:
- e) a plurality of second decoder means, each coupled to a respective one of said plurality of cause register means, each said second decoder means for indicating information about contents of a respective cause register means; and
- f) an event history buffer means for storing information regarding processor events, said history buffer means having a data input, a data output, and an enable input, said data input being coupled to each of said plurality of cause register means and said enable input being coupled to each of said second outputs, wherein

each of said second decoder means decodes contents of a respective cause register means and enables said event history buffer to capture contents of said respective cause register means when contents of said respective cause register means indicate a particular event.

17. An embedded system according to claim 16, wherein:

each said second decoder means enables said event history buffer means when contents of a respective cause register means indicate an event including at least one of a change in status of an interrupt line, an internal processor exception, and a jump instruction based on the contents of a register.

- 18. An embedded system according to claim 16, wherein:
  said data output of said event history buffer means is a bit
  serial output.
- 19. An embedded system according to claim 11, wherein:
  said system is embodied on a chip having a plurality of pins,
  said first and second outputs are provided via some of said
  plurality of pins.
- 20. An embedded system according to claim 19, wherein: each of said first outputs is an n-bit parallel output, and said second output is a serial output.
- 21. A method of debugging a processor, said method comprising:
- a) providing information about processor activity in real time;
   and
- b) associating the instructions executed by the processor with the information about processor activity.

22. A method according to claim 21, wherein:

said step of providing information about processor activity includes providing information about every instruction executed by the processor.

23. A method according to claim 22, wherein:

said step of providing information about processor activity includes providing information that the processor has not executed an instruction during the last processor cycle.

24. A method according to claim 21, wherein:

the information about processor activity includes an indication of at least one of whether the last instruction executed was a jump, a jump based on the contents of a register, a branch taken, or an instruction which encountered an exception.

- 25. A method according to claim 21, further comprising:
- c) providing information regarding the status of the processor when certain processor events occur, said certain processor events including at least one of a change in status of an interrupt line, an internal processor exception, and the execution of a jump instruction based on the contents of a register.

A debugging interface includes a pair of decoders and an event history buffer coupled to the sequencer of a processor. first decoder is coupled to the program counter of the sequencer and the Instruction RAM of the processor. The second decoder is coupled to the cause register of the sequencer and the event history buffer is also coupled to the cause register. The first decoder provides a three bit real time output which is indicative of the processor activity on a cycle by cycle basis. bit output indicates seven different conditions: whether the last instruction executed by the processor was an inc, an exception, an exception with no event history buffer entry, or a branch taken, whether there has been no instruction executed since the last clock cycle, and whether a jump was an immediate jump or a jump to a register. The event history buffer is loaded with more detailed information about the instruction last executed when the first decoder indicates that the last instruction was an exception or a jump to a register, and when there is a change in state of an interrupt line or an internal processor exception. An exemplary implementation of the debugging interface is embodied on an ASIC chip having three processors. Each processor is provided with a first and second decoders and a single event history buffer for all processors is provided on the chip.

#### DECLARATION FOR PATENT APPLICATION AND POWER OF ATTORNEY

As below named inventor, I hereby declare that:

My residence, post office address and citizenship are as stated below next to my name, and

I believe I am the original, first and sole inventor (if only one name is listed below) or an original, first and joint inventor (if plural names are listed below) of the subject matter which is claimed for and for which a patent is sought on the invention entitled

### REAL TIME DEBUGGER INTERFACE FOR EMBEDDED SYSTEMS,

the specification of which

[ <b>X</b> ]	is attached hereto.	
[ ]	was filed on	
	as application Serial Number	
	and was amended on (if applicab	ole)
above ide	state that I have reviewed and entified specification, including referred to above.	
examinat:	ledge the duty to disclose infor ion of this application in accor Regulations, Section 1.56(a).	mation which is material to the dance with Title 37, Code of
Code of 1 rights to	that I am qualified as an indep Federal Regulations, Section 1.9 this invention, if any, is to under Title 37, Code of Federal	endent inventor under Title 37, (c), and my obligation to assigr a qualified small business Regulations, Section 1.9(d).
Code, Sec certifica applicat:	claim foreign priority benefits ction 119 of any foreign applica ate listed below and have also i ion for patent or inventor's cer hat of the application on which	tion(s) for patent or inventor's dentified below any foreign tificate having a filing date
Prior For	reign Application(s)	Priority Claimed
(Number)	(Country)	/_/[] YES [] NO D/M/YR FILED
(Number)	(Country)	// [ ] YES [ ] NO
I hereby	claim the benefit under Title 3	5. United States Code Section

I hereby claim the benefit under Title 35, United States Code, Section 120 of any United States application(s) listed below and, insofar as the subject matter of each of the claims of this application is not disclosed in the prior United States application in the manner provided by the first paragraph of Title 35, United States Code, Section 112, I

acknowledge the duty to disclose material information as defined in Title 37, Code of Federal Regulations, Section 1.56(a) which occurred between the filing date of the prior application and the national or PCT international filing date of this application:
(Application Ser. No) (Filing Date) (Status-Patented, pending, abandoned)
(Application Ser. No) (Filing Date) (Status-Patented, pending, abandoned)
As a named inventor, I hereby appoint the following attorney(s) and/or agent(s) to prosecute this application and transact all business in the Patent and Trademark Office connected therewith:
David P. Gordon (29,996), David S. Jacobson (39,235), Thomas A. Gallagher (31,358)
Address all telephone calls to David P. Gordon at (203) 329-1160  Address all correspondence to David P. Gordon, Esq.  65 Woods End Road  Stamford, Connecticut 06905  U.S.A.
I hereby declare that all statements made herein of my own knowledge are true and that all statements made on information and belief are believed to be true; and further that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under Section 1001 of Title 18 of the United States Code and that such willful false statements may jeopardize the validity of the application or any patent issued thereon.
SOLE OR FIRST INVENTOR
Signature Date
